▼ Detaljer

Introduction

You are to design and implement a blog where registered users can create and edit blog posts. For this you need a system to register and authenticate users, lucky for us this is automatically included if you use the right project type. Create the project inside your *solutions* git directory, now **with authentication**.

Deliver on your personal git repository under the directory "assignment_4".

Note: Your project **MUST** have a database initializer that does `.EnsureDeleted()` and `.EnsureCreated()`. Otherwise the tests won't find a database.

Functional requirements

- Users must be able to register an account
 - Default identity URLs
 - Users must be able to log in
 - Default controller and action names
 - Additional required field in `Account.Register`:
Nickname
- Users must be able to write new posts
- Users must be able to edit their own posts
- Everyone must be able to see existing posts

Technical requirements

Your controller must be called *BlogController*.

Actions must be called:

- **Index**
 - Shows the current blog posts by all users, sorted by newest first.
 - Each post must use the following CSS classes:

- Nickname of the user that posted it with class 'Nickname' (Custom field in ApplicationUser)
- Title with class 'Title'
- Summary with class 'Summary'
- Content with class 'Content'
- Timestamp with class 'Time' and format: '12.09.2023'
- **Add**
 - Contains the form to write another post:
 - Title with id 'Title'
 - Summary with id 'Summary'
 - Content with id 'Content'
 - Button with id 'Submit'
- **Edit**
 - Contains the form to edit an existing post, using an id in the URL, like this: /Blog/Edit/1.
 - Same fields and IDs as the Add action.

The index action must show a timestamp of when the post was written. The edit action must verify that the currently logged in user owns the blog post.

Requirements:

- Each post must be displayed using a partial view called *_PostPartial*

Areas of interest

See Entity Framework and Identity Framework lectures for details. For the client you will need to design the user interface as you have done before. For the server it might be easiest to start building the blog post model, then build the view for it, then the controller.
